0. Introduction

This paper examines the Mandarin system of non-verbal predication and the use of copula morphemes within that system, taking the Copula Support Hypothesis (CSH) as developed by Dik (1980, 1983, 1985) within the framework of Functional Grammar (FG) as a point of departure. The CSH is based on the assumption that the copula is a semantically empty supportive device, whose main function is to carry those grammatical distinctions which cannot be expressed otherwise in a given language. The basic idea behind the CSH is that an approach in which the copula is inserted only in those contexts in which it is required is psycholinguistically and typologically more adequate than an approach in which the copula is first generated in all underlying structures containing a non-verbal predicate and afterwards deleted in those contexts in which it does not have to appear. In fact, the constraints which FG imposes on possible grammars would disallow the latter approach.

Linguistic expressions are represented in FG in underlying predications, in which semantic functions (Agent, Goal, etc.) specify the relation between the participants in the State of Affairs (SoA) designated by that predication, syntactic functions (Subject, Object) the perspective from which the SoA is presented, and pragmatic functions (Topic, Focus, Theme, Tail) the informational status of the arguments. To form a predication the speaker selects a predicate frame from the lexicon, such as:

(1) \( \text{give}_V (x_1) \text{Ag} (x_2) \text{Go} (x_3) \text{Rec} \)
This predicate frame provides the information that give is a verbal predicate which takes three arguments with the semantic functions Agent, Goal, and Recipient. Through term insertion into the argument slots of the predicate frame and specification of the relevant operators a predication like the following is reached:

(2) \( \text{Past give}_v (dlx_1: \text{Mary (} x_1 \text{)})_A (ilx_j: \text{book (} x_j \text{)})_G (dlx_k: \text{John (} x_k \text{)})_R \)

Terms are referring expressions of the following general format:

(3) \( (\forall x_1: \phi_1(x_1); \phi_2(x_1); \ldots; \phi_n(x_1)) \)

in which \( x \) is a term variable, \( \phi \) a predicate and \( \forall \) represents one or more term operators. Each \( \phi(x) \) constitutes an 'open predication in \( x \)' which further restricts the set of potential referents of the term.

Operators represent grammatically coded semantic distinctions. Term operators capture distinctions like definite (d) versus indefinite (i) and singular (1) versus plural (m). Predicate operators capture distinctions generally coded on or near the predicate, such as Tense, Mood, Aspect, and Polarity.

The final expression of an underlying predication is handled by expression rules, which in the case of (2) would have to result in:

(4) Mary gave a book to John

Verbal and non-verbal predicates are represented in the same way in the lexicon. Thus, instead of (1) the speaker may select (5):

(5) \( \text{clever}_A (x_1) \phi \)

This predicate frame provides the information that clever is an
adjectival predicate which takes one argument with the semantic function Zero. It is in the expression of underlying predications built on non-verbal predicate frames that a rule of Copula Support becomes relevant. Consider the following underlying predication:

(6) \text{Pres clever}_\text{A} (x_1: \text{Mary} (x_1))\phi

In the final expression of this underlying predication the copula will have to appear. This is ensured by a Copula Support Rule of the following general format:

(7) COPULA SUPPORT

\text{input: } \pi \text{ predicate}_\beta (x_1) (x_2) \ldots (x_n)

\text{conditions: } \pi = \ldots
\beta = \ldots
\ldots = \ldots

\text{output: } \pi \text{ copula}_\gamma \text{ predicate}_\beta (x_1) (x_2) \ldots (x_n)

The conditions to be specified in the rule are language specific: in some languages certain predicate operators (\pi) will trigger copula support, in others the predicate type (\beta), properties of the argument (x), or other factors will be relevant. Possibly some languages will not need a copula support rule at all. If they do, the copula type (\gamma) is relevant. To account for the appearance of the copula be in English Dik (1983) formulates the following rule:

(8) BE SUPPORT

\text{input: } \pi \text{ predicate}_\beta (x_1) (x_2) \ldots (x_n)

\text{conditions: } \pi = \text{ any specified predicate operator }
\beta \neq \gamma

\text{output: } \pi \text{ be}_\gamma \text{ predicate}_\beta (x_1) (x_2) \ldots (x_n)

This rule is based on the idea that the appearance of a copula in English is a result of the fact that all predicate operators need
to be expressed on a verbal predicate. In all cases in which no such verbal predicate is present, the empty verb *be* is inserted. Application of rule (8) to (6) results in:

\[(9) \quad \text{Pres } \text{be}_V \text{ clever}_A (x_1 : \text{Mary} (x_1)) \phi \]

which will be expressed as:

\[(10) \quad \text{Mary is clever} \]

Apart from bare non-verbal predicates there are also derived non-verbal predicates. Among them are predicates derived from terms, as in:

\[(11) \quad \text{A cat is an animal} \]

and predicates derived from terms provided with a semantic function, as in:

\[(12) \quad \text{The cat is in the garden} \]

The term 'adpositional predicate' will be used in this paper to refer to the latter predicate type. The predicates involved are produced by a predicate formation rule of the following format (see Dik 1980):

\[(13) \quad \text{TERM-PREDICATE FORMATION} \]

\[\text{Input: } (t)(sf) \]
\[\text{Output: } ((t)(sf)) (x_1) \phi \]

Other types of non-verbal predicates will be introduced in section 3.

Being an analytic language, Mandarin Chinese is particularly interesting in the context of the copula support hypothesis. The hypothesis predicts that in analytic languages, in which grammatical distinctions are expressed in separate morphemes, and not
marked on a (verbal) predicate, the presence of the operators involved would not be a triggering condition for the appearance of a copula. Therefore, one would expect that if such a language makes use of one or more copulas, these uses should depend crucially on other triggers, such as properties of the predicate or the φ-argument, and that these triggering conditions have a different explanation.

The organization of this paper is as follows. In section 1 the basic uses of the Mandarin copulas shi and you are summarized. These uses do not present any particular problem to the approach outlined above. In the next sections some constructions are studied in greater detail: constructions with you in section 2, and with shi in section 3. Section 4 is concerned with non-verbal auxiliary constructions. In section 5 I try to relate the findings to the general principles underlying the CSH. In conclusion, I propose a number of rules to capture these findings. Unless indicated otherwise, examples used in this paper are taken from Li & Thompson (1981).

1. Basic uses of shi and you

Mandarin has two copulas: shi, which is optional except if negated, and you. You has a negative counterpart, mei, which may optionally be followed by you. The main uses of the copulas are:

No copula:

(1) Adjectival predicates
(14) ta hen pang
    3sg very fat
    'He is very fat'

Adpositional predicates with a definite φ-argument
(15) Lisi zai hai-bian
    Lisi LOC sea-side
    'Lisi is at the coast'
6 Kees Hengeveld

Shi:

(1) Term-predicates.

(16)a Zhangsan (shi) yi-ge hush1
Zhangsan (COP) one-CL nurse
'Zhangsan is a nurse'

b Wo bu shi Zhongguo-ren
lsg not COP China-person
'I'm not a Chinese'

You / Mei(you)

(1) Adpositional predicates with an indefinite $\phi$-argument.

(17) You yi-ge ren zai waimian jiao-men
COP one-CL person LOC outside knock-door
'There's someone outside knocking at the door'

Informally, these different uses are captured by the following representations:

(18) No copula: $\text{Pred}_{A^1} \ (\{x_1\}_{sf}) (dx_1)_{\phi}$

(Shi): $\{\{x_1\}\} (x_1)_{\phi}$

You / Mei(you): $\{\{x_1\}_{sf}\} (lx_1)_{\phi}$

In the following sections some of these constructions will be studied in more detail.

2. The existential copula you

In section 1 you was characterized as a copula which is used in the context of an adpositional predicate with an indefinite $\phi$-argument. Some examples are:

(19) You yi-ge ren dou-le
COP one-CL person shake-PF
'There was someone who shook'
(20) (Zai) wuzi-li you san-ge ren
(LOC) house-in COP three-CL person
'In the house, there are three people'

(21) You yi-zhi gou zai yuanzi-li
COP one-CL dog LOC yard-in
'There's a dog in the yard'

(22) Ta you san-ge haizi
3sg COP three-CL children
'He has three children'

These examples illustrate that you can be used in existential (19), locative (20)-(21), and possessive (22) constructions.

2.1. Existential and locative constructions

For the analysis of existential constructions Dik (1980:ch.4)) proposed the following structure:

(23) \{((-\phi)_{\text{Loc}}) (1x_1): \phi\}

This representation is based on the idea that existence can be viewed as 'being situated at an unspecified location', and predicts a correspondence between existential and locative constructions: their underlying structure is the same, but in locative constructions the location is specified, whereas in existential constructions it is not. This analysis can be applied straightforwardly to (19) and (21):

(24) \{((-\phi)_{\text{Loc}}) (1lx_1: \text{ren}_N (x_1)): \text{Pf} \ \text{dou}_V (\text{Rx}_1)) : \phi\}

(25) \{((x_1: \text{yuanzi-li}_N (x_1))_{\text{Loc}}) (1lx_2: \text{gou}_N (x_2)): \phi\}

The situation with respect to (20) is less clear cut. The preposition zai 'at' is optional if it is in initial position (in presentative constructions, see Li & Thompson 1981, ch.17), whereas it is obligatory in other contexts, such as (21) and (26):
An implication of the Theme analysis of possessive and locative constructions with a sentence-initial constituent specifying possessor or location is that the two constructions are structurally similar if the locative semantic function is not expressed. This fits in with the observation in Li & Thompson (1981:513) that the similarity of you constructions resides in the fact that '... something is being claimed to exist; the difference is whether it is said to exist with respect to a place or to another entity'.

3. The classifying copula shí

In section 1 the basic function of the optional copula shí was characterized as linking a term and a term-predicate. Many of the different uses of shí can be explained in this way, in particular its use with predicates containing an adjectival or possessive predicate (3.1). Other uses ask for a refinement of this basic definition: its use as a focus marker (3.2), and its occurrence in veridical constructions (3.3).

3.1. Adjectival and possessive predicates

As stated in section 1 adjectival predicates do not require a copula to appear. Not all adjectival predicates, however, can be put to predicative use. Consider the following example:

(34) nei-feng xin (shí) jia de
    that-CL letter COP fake NOM
    'That letter is a fake'

The adjective jia is nominalized by means of the particle de and treated as a term-predicate, witness the optional appearance of shí. According to Li & Thompson (1981) the adjectives which behave in this way can be roughly characterized as absolute adjectives. Scalar adjectives can be applied as a predicate without further measures being taken. The particle de in (34) deserves
some attention. It has been characterized as a nominalizer, but is in fact a multi purpose particle, which can be used to introduce all kinds of restrictors of the head of a term, such as relative clauses (35), associative phrases (36), possessive phrases (37), and adjectives (38):

(35) Zhangsan mai de qiche
    Zhangsan buy de car
    'The car that Zhangsan bought'

(36) ke xue de fazhan
    science de development
    'The development of science'

(37) ni-de nei-ben shu
    2sg-de DEM-CL book
    'That book of yours'

(38) pang de ren
    fat de person
    'A fat person'

In all cases, the main function of de is to mark restrictors of the head noun. Since in FG the head noun too is conceived of as a restrictor of the term variable, one could say that de introduces non-first restrictors. Given this basic function of de its nominalizing function can be explained. Since de is used only to introduce non-first restrictors, its appearance in, for instance, the predicate in (34), jia de 'a fake', indicates that a first restrictor is understood. A possible paraphrase for (34) could be: 'that letter is a fake letter', or: 'that letter is a fake one'. To account for these facts an underlying structure like the following, adapted from de Groot (1983), may be hypothesized:

(39) \{<x_1: A^N_N(x_1); jia_A(x_1)> \}<x_j: x1n(x_j)}

Jia de 'a fake' is analyzed in (39) as a term-predicate, derived from a term in which the first restrictor is an anaphoric nominal predicate, restricted by the adjective jia 'fake'. The optional appearance of shi runs parallel to its appearance with other
term-predicates.

A similar phenomenon may be observed in possessive constructions in which the term referring to the possessed entity is definite. Consider:

(40) Chensan (shi) wo-de
    Shirt (COP) 1sg-de
    'The shirt is mine'

Again we find the particle de and an optional copula shi. The appearance of de in constructions like these might lead one to assume that de is a genitive marker, but given the analysis of de as a particle introducing non-first restrictors another representation is possible, which runs parallel to (39):

(41) \(((x_i: A\Phi_N (x_i): ((x_j: wo (x_j))_{\text{Poss}}(x_i)))(x_k: chensan (x_k))\)φ

De Groot (1983) proposed this representation for one type of possessive construction in Hungarian. Like jia de 'a fake one' in (39), wo de 'mine' in (41) is analyzed as a term-predicate, derived from a term in which the first restrictor is an anaphoric nominal predicate, restricted by the possessive predicate wo. The appearance of de is triggered by the presence of a second restrictor within the term-predicate. Note that an implication of this analysis is that the semantic function Possessor has no expression in Mandarin Chinese. This is consistent with the findings in 3. The term-predicate analysis of possessive constructions of the type under discussion furthermore explains the optional appearance of shi.

The structural similarity between term-predicates derived from an absolute adjective and those derived from a possessive predicate asks for some closer attention. First of all, note that it is not only in the predicative domain that adjectives and possessive predicates behave similarly. Examples (37)-(38), repeated here as (42)-(43), showed part of their similarity in the attributive domain:
(42) ni-de nei-ben shu
2sg-de DEM-CL book
'That book of yours'

(43) pang de ren
fat de person
'A fat person'

If there is a close connection between the entity and the property attributed to that entity the particle de can be omitted both if the restrictor is an adjective and if it is a possessive predicate:

(44)a hong de hua
red de flower
'a red flower'

b hong hua
red flower
'a red flower'

(45)a ni de nei-ben shu
1sg de DEM-CL book
'that book of yours'

b ni nei-ben shu
1sg DEM-CL book
'your book'

To explain this similarity in behavior of (absolute) adjectives and possessive predicates let me turn to a possible extension of the copula support theory. Until now I have treated terms as if they constituted a single undifferentiated category. Terms may, however, refer to different kinds of entities. In the present context a subclassification according to whether the terms in question refer to a first, second or third-order entity (see Lyons 1977:442-3) is useful. Physical objects belong to the class of first-order entities, SoA's to the class of second-order entities, and propositions to the class of third-order entities. First-order entities can be evaluated with respect to their location, second-order entities with respect to both their location and time of occurrence, and third-order entities with respect to neither of these two concepts. Not all kinds of predicates can be applied to all kinds of entities. The following table gives an overview of some of the possible combinations. For each possible combination a label indicating the semantic relation expressed by that combination is provided. To distinguish between terms referring to first, second, and third-order entities the variables x,
(46) SEMANTIC RELATIONS IN NON-VERBAL PREDICATION

<table>
<thead>
<tr>
<th></th>
<th>(x_1)</th>
<th>(e_1)</th>
<th>(X_1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>({x_1}_{\text{Poss}})</td>
<td>Possession</td>
<td>--</td>
<td>--</td>
</tr>
<tr>
<td>({x_1}_{\text{Loc}})</td>
<td>Location</td>
<td>Occurrence</td>
<td>--</td>
</tr>
<tr>
<td>({\phi}_{\text{Loc}})</td>
<td>Existence</td>
<td>Reality</td>
<td>--</td>
</tr>
<tr>

<td>--</td>
<td>Time</td>
<td>--</td>
</tr>
<tr>
<td>Pred(_A)</td>
<td>Property ass.</td>
<td>Evaluation</td>
<td>Judgment</td>
</tr>
</tbody>
</table>

What is indicated in this table is that possession can be predicated of concrete objects, but not of SoA's and propositions; that both concrete entities and SoA's can be located, but not propositions; and so on. Adjectival predicates (as a class) can be applied to all kinds of entities, but there are restrictions with respect to the subclasses of adjectives to be applied to the different types of entities. Physical objects can have properties such as 'alive', 'big' or 'red', SoA's properties such as 'possible' or 'regrettable', and propositions properties such as 'true'. If we look at the possibility to apply scalar and absolute adjectives to first and second-order entities the following picture emerges:

(47) ABSOLUTE AND SCALAR ADJECTIVES

<table>
<thead>
<tr>
<th></th>
<th>(x_1)</th>
<th>(e_1)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pred(_A)-abs.</td>
<td>Property ass.</td>
<td>--</td>
</tr>
<tr>
<td>Pred(_A)-sc.</td>
<td>Property ass.</td>
<td>Evaluation</td>
</tr>
</tbody>
</table>

The evaluative nature of adjectives which can be applied to se-
cond-order entities seems to be incompatible with the character of absolute adjectives, which therefore generally cannot take a predication as their argument, whereas scalar adjectives can, as illustrated in (48)-(49):

(48) zai nali mai dongxi hen mafan
    LOC there buy thing very troublesome
    'It's a lot of trouble to shop there'

(49) zheige biao huai le zhen kexi
    this-CL watch broken PERF real regrettable
    'It is really regrettable that this watch has broken'

What we find then is that the two classes of predicate which apply to first-order entities only are the two classes which cannot be used predicatively in Mandarin Chinese. The special treatment given to these predicates can be seen as a measure to restrict these two types of predicate to the attributive domain.

3.2. Focus constructions

Consider the following sentences, taken from Teng (1979):

(50) zai gongyuan-li zhao-dao ni de gou de shi wo
    LOC park-in find-ASP 2sg de dog de COP 1sg
    'The one who found your dog in the park was I'

(51) Shi wo zai gongyuan-li zhao-dao ni de gou de
    COP 1sg LOC park-in find-ASP 2sg de dog de
    'It was I who found your dog in the park'

These sentences are examples of the pseudo-cleft and cleft construction in Mandarin. Dik (1980:ch.10) argues that cleft and pseudo-cleft constructions are focus constructions which can be analyzed as identifying constructions. What is identified is 'an entity of which the existence is presupposed'. In (50)-(51) this presupposed entity is described in the form of a headless relative and its identity is given in the form of a focused term-predicate, as represented in (52):
(52) $\{(x_i, \text{ wo } (x_i))_{\text{FOC}} \mid (x_j, \text{ Asp } \text{ Zhao}, (Rx_j)(x_k, \text{ gou } (x_k)), \{(x_i, \text{ ni } (x_i))_{\text{POSS}}) (x_k))\}$.

This term-predicate analysis of cleft and pseudo-cleft* constructions explains the appearance of shi.

By the side of (50)-(51), one finds constructions like the following (Teng 1979):

(53a) Shi wo mingtian dao Niu Yue qu
    shi 1sg tomorrow DIR New York go
    'I am going to New York tomorrow'

(53b) Wo shi mingtian dao Niu Yue qu
    'I'm going to New York TOMORROW'

(53c) Wo mingtian shi dao Niu Yue qu
    'I'm going TO NEW YORK tomorrow'

The use of shi in these examples coincides with the ones given in (50)-(51), in that it precedes the (underlined) focused constituent, but it differs in that the particle de, marking the headless relative, is absent and in that it does not link a clearly separated term-predicate and a $\phi$-argument. The function of shi seems to be simply that of marking the focused constituent. Even the predicate may be focalized in this way, as in (53d) (Shen p.c.):

(53d) Wo mingtian dao Niu Yue shi qu
    'I'm GOING to New York tomorrow'

There is evidence from other languages that focus markers may develop out of copulas. The following examples are from Wambon, a Papuan language (see de Vries 1986):

(54) ev-o lan-e kolamop-nde
    DEM-CONN woman-CONN long-COP
    'That woman is long'
(55)  woyo, lakhai-nde takhimo-knde  
    No, fish-FOC buy-3PL.PRES  
    'No, they buy FISH'

Like de Vries (1986:31), I take it that the source of this development is the cleft/pseudo-cleft focus construction. The following stages may be hypothesized to account for this development:

(56)  FROM COPULA TO FOCUS MARKER

(i)  Cleft/Pseudo Cleft construction
(ii)  Loss of relative clause characteristics/Focus marker bound to a specific position
(iii)  Generally applicable focus marker

Stage (ii) can be observed in English, as shown in the following examples:

(57)a  It's Mary wants the book  
   b  It's the book Mary wants  
   c  It's to the party Mary goes  

(58)a  *Mary wants it's the book  
   b  *Mary goes it's to the party

The Mandarin copula shi seems to have reached stage three. The examples in (53) show that, unlike be in English, shi may occupy any position. I conclude, therefore, that shi has developed a secondary function as focus marker.

This analysis may at the same time shed some light on what has been called the 'illogical' copula construction, as exemplified in (59), taken from Hashimoto (1969):

(59)  wo  shi  jifan  
    lsg shi chicken-rice  
    'I -- chicken-rice'

A literal translation of (59) would be: 'I am chicken rice',
which is not the intended reading. Another example is:

(60)  wo shi Zhangsan
       1sg shi Zhangsan
       'I -- Zhangsan'

Of course this is a 'logical' copula sentence if it is uttered by Zhangsan, but what is intended here is a situation in which someone else utters (60).

Sentences like (59)-(60) can only be understood within the context in which they are used. So, for instance, (59) would be appropriate in the following context:

(61)  nimen jiao le shenme cai a? :: wo shi jifan,
       2sg  order PP what  dish PP? :: 1sg shi chicken-rice,
       ta shi ... 
       3sg shi ...
       'What have you ordered? :: I -- chicken-rice, he -- ...'

And (60) can be used in a context like:

(62)  nimen xuan le shi a? :: wo shi Zhangsan, ta shi ...
       2sg  vote.for PP who PP? :: 1sg shi Zhangsan, 3sg shi ...
       'Who have you voted for? :: I -- Zhangsan, he -- ...'

According to Li & Thompson (1981:150) sentences like (59)-(60) indicate that, in an appropriate context, shi 'allows a very loose linkage or connection between the referential subject noun phrase and the non-referential noun phrase following the copula'. I would like to consider another possible analysis.

The contexts given in (61)-(62) seem to indicate that shi substitutes for verbs which have been mentioned in the immediately preceding conversation. Hashimoto (1969:90) uses the term 'pro-verb' to characterize this use of shi. A representation like the one given in (63) could capture this characteristic:
(63) $A^\Phi_V (dx_1: wo (x_1))_{Ag} (ix_j: jifan (x_j))_{Go}$

The anaphoric predicate would then have to be expressed as *shi* by the final expression rules. But, as (61)-(62) show, the 'illogical' copula appears in contexts in which the constituent following *shi* is focalized. This brings me to an alternative analysis, given in (64):

(64) $A^\Phi_V (dx_1: wo (x_1))_{Ag} (ix_j: jifan (x_j))_{Go}F_{oc}$

This representation differs from (63) only in that Focus is assigned to the Goal argument. The appearance of *shi* can now be attributed to the presence of this Focus marker, as in the case of sentences like (59)-(60), while the understood predicate remains unexpressed, just like the anaphoric predicates discussed in 3.1. The same analysis can be applied to sentences like the following, which would be more difficult to capture within a pro-verb analysis:

(65) daochu dou shi xue
everywhere all COP snow
'What's everywhere is snow'

where one would expect (see section 2):

(66) daochu dou you xue
everywhere all COP snow
'There's snow everywhere'

As the translation suggests, (65) identifies a presupposed entity located everywhere, whereas (66) presents an entity located everywhere. Or, as Chao (1948:153), cited by Hashimoto (1969:89) puts it, for (65) 'it is understood that there is something everywhere, and it is snow', whereas for (66) 'there might or might not be anything anywhere, but actually there is something—snow'. *Shi*, then, is used in constructions in which an entity, the existence of which is presupposed by the Addressee, is identified, whereas *you* is used to present new referents. Again
shi precedes the focused constituent. If it is, therefore, analyzed as a focus marker in constructions like these too, the question remains which predicate is understood in sentences like (65). Recall that in section I gave the following representation for locative constructions with an indefinite \( \phi \)-argument:

\[
(67) \quad (x_1)_{\text{Theme'}} (\phi)_{\text{Loc'}} (x_j) \phi
\]

Suppose now the presupposed entity identified in constructions like (65) is introduced in a question like:

\[
(68) \quad \text{Everywhere, there's what?}
\]

Following the pattern given in (67), what is then missing in (65), if shi is regarded as a focus marker, is the empty locative predicate. The missing predicate in 'illogical' copula sentences, then, is not necessarily a verb, as in (59)-(60), but can be of the non-verbal type too. This leads to the following general representation for 'illogical' copula sentences:

\[
(69) \quad ((x_1)_{\text{Theme'}}) A^\alpha \ldots (x_n)_{\text{Foc}} \ldots
\]

The occurrence of shi can be accounted for by a rule like:

\[
(70) \quad (x_n)_{\text{Foc}} \longrightarrow \text{shi} (x_n)
\]

3.3. Veridical constructions

The term 'veridical construction' is used here, following Kahn (1973), to refer to those constructions through which the speaker expresses his attitude with respect to the truth of a proposition given in the context. Here are some examples:

\[
(71) \quad \text{Bu shi wo bu yao lai, shi ta bu rang wo lai}
\quad \text{NEG COP 1sg NEG want come, COP 3sg NEG let 1sg come}
\quad \text{'It's not that I don't want to come, it's that she won't let me come'}
\]
Before going into the analysis of the use of the copula in the constructions given here let me return to the basic distinction between first, second and third-order entities, which has been applied to property-assigning expressions in 3.1. Given that terms may refer to either of these three types of entity, one expects that term-predicates can be classified according to the type of the term from which they are derived, as in:

(73) **TERM-PREDICATES**

<table>
<thead>
<tr>
<th>((x₁)) (x₁)ϕ</th>
<th>Entity classification</th>
</tr>
</thead>
<tbody>
<tr>
<td>((e₁)) (e₁)ϕ</td>
<td>SoA classification</td>
</tr>
<tr>
<td>((X₁)) (e₁)ϕ</td>
<td>Proposition classification</td>
</tr>
</tbody>
</table>

Examples of the first and second predicate type are:

(74) ta fuquin shi waijiao buzhang
3sq father COP foreign.affair minister
'His father is the foreign minister'

(75) ni bu qu jiu shi bu fucong mingling
2sq NEG go EMPH COP NEG obey command
'Your not going is disobedience of command'

In fact, it would be better to term the second and third predicate type, to which I will turn my attention presently, 'predication-predicates'. "The motivation for this approach will become clear if the different variables are situated in a model for the clause." In my view, an utterance can be analyzed in terms of the following schema:
(76) \[ E_1: \text{ILL}(X_1: \text{[predication]}(X_1)) (E_1) \]
\[ e_1: \text{Pred}_\beta (x_1) (x_2) \ldots (x_n) (e_1) \]

At the lowest level the general structure for the predication in FG is presented as a restrictor of the SoA-variable \( e \). This level represents the narrated event. At the highest level the speech event \( (E) \) is structured on the basis of an illocutionary frame, which represents the basic illocution of the linguistic expression involved. The content of the utterance (the proposition \( X \)) is seen here as a participant in the speech event, together with Speaker and Addressee. Dik (forthc.) proposes that the basic illocutions of linguistic expressions be represented by means of illocutionary operators which take a predication in their scope.\(^*\) The paraphrase he gives for, for instance, the DECL(ative) operator has to be adapted slightly to apply to the DECL(ative) frame which is used in the approach outlined above:

(77) \[ \text{DECL}(X_1) \] Speaker wishes the Addressee to add the content \( X_1 \) to his pragmatic information.

Given the analysis presented in (76), every utterance \( (E) \) introduces, or refers to, three kinds of referents: propositions \( (X) \), SoA's \( (e) \), and entities \( (x) \).

In the context of the veridical constructions in Mandarin as exemplified by (71)-(72) it is especially the possibility to refer to propositions that is relevant. Crucial for such a construction is that it '... strongly affirms (or denies KH) a piece of information in earlier discourse which now follows the shi' (Li & Thompson 1981:154). In (71) a piece of information is denied and replaced by another, in a contrastive sense. In (72) a piece of information is simply affirmed. Supposing now that the affirmed or denied piece of information has the indexed proposition variable \( X_1 \), then (71)-(72) can be represented, somewhat simplified, as:
(78) \[ \text{DECL}(X_K): \text{Neg } \{ (X_J: \text{wo bu yao lai } (X_J))_{\text{FOC}} \{ X_K \} \}, \]
\[ \text{DECL}(X_K): \text{Pos } \{ (X_M: \text{ta bu rang wo lai } (X_M))_{\text{FOC}} \{ X_K \} \} \]

(79) \[ \text{DECL}(X_K): \text{Pos } \{ (X_J: \text{bu chi la de } (X_J)) \{ X_K \} \} \]

Paraphrases for (78)-(79) are (80)-(81):

(80) 'The content which I wish you to add to your pragmatic information is not \( X_J \) but positively \( X_M \).

(81) 'The content which I wish you to add to your pragmatic information is positively \( X_J \).

Veridical constructions in Mandarin can thus be classified as based on a predicate of the third type given in (76), expressing the semantic relation of proposition classification, more in particular, proposition identification. The rule for term-predicate formation given in section 1 may now be reformulated as a term/predication-predicate formation rule, as in (82), in which \( \alpha \) stands for \( x, e, \) or \( X \):

(82) \[ \text{TERM/PREDICATION-PREDICATE FORMATION} \]
\[ \text{Input: } \{ (\alpha_1)(sf) \} \]
\[ \text{Output: } \{ (\alpha_1)(sf) \{ (\alpha_1)\} \} \]

Note that, apart from the realization of \( \alpha \), there is a strong correlation between the focus constructions dealt with in 3.2 and the veridical constructions treated here. This correlation is reflected in the ambiguity of the following sentence, if intonation contour is left out of consideration:

(83) \[ \text{shi wo zai nar da gu} \]
\[ \text{COP 1sg LOC there hit drum} \]
\[ '\text{It's I who's been playing drums over there}' \] or:
\[ '\text{It's true that I've been playing drums over there}' \]

The first interpretation is appropriate if heavy stress is put on
wo 'I', the second if heavy stress is put on shi 'be' (see Li & Thompson 1981:153-4).

In 3.2 it was pointed out that languages may develop a focus marker out of a copula. Similarly, some languages may develop an assertive marker out of a copula. The appearance of shi near the predicate in sentences like (72) might indicate that shi is developing in the same direction. This would be a second parallelism between the uses of shi in focus and veridical constructions.

4. Non-verbal auxiliary constructions

To complete the picture of the Mandarin system of non-verbal predication, this section is concerned with those non-verbal constructions which have developed a specific grammatical meaning, in the sense that they are used to give expression to aspectual distinctions. Each of the three possible constructions (without a copula (4.1), with the copula you (4.2), with the copula shi (4.3)) has such a specialized application.

The idea that auxiliary copula constructions can be analyzed as special instances of non-verbal predication was first put forward in Dik (1983) and further developed in Dik (1985). Language specific proposals in the same field have been made by de Groot (1987), Hengeveld (1986), and Shiratsuki (1985).

4.1. Non-verbal auxiliary constructions without a copula

Consider the following examples:

(84) Lisi zai jieshi wenfa
    Lisi DUR explain grammar
    'Lisi is explaining grammar'

(85) Zhangsan zai da Lisi
    Zhangsan DUR hit Lisi
    'Zhangsan is hitting Lisi'
The durative aspect marker zai which appears in these examples is identical to the preposition which introduces locative arguments. Dik (1985) discusses the 'localist channel' as one of the possible origins of copula auxiliarization, which in this case would be the result of the conceptualization of a SoA as a spatial object. The absence of a copula in (84)-(85) does not affect the analysis; in fact it supports it, since in the non-verbal construction which would be the source for the auxiliary construction exemplified here, it would be absent too. The following representation could be given to (84):

\[(86) \{ (e^i_1; \{ jieshi^v (x^i_1)^\text{Ag} \ (x^j_1; \text{wenfa}_N (x^j_1)^\text{Go})_\text{Loc} \} (x^i_1; \text{Lisi}_N (x^i_1))^\emptyset \}

A literal paraphrase of this representation would be: 'Lisi is in the explaining of grammar'. Whether the above representation can be said to be synchronically relevant is hard to say. Nevertheless, it seems a likely source for the durative aspect marker zai.

4.2. Non-verbal auxiliarly constructions with the copula you.

Li & Thompson (1981:ch.12) point to an interesting phenomenon in the speech of southern speakers of Mandarin. Under the influence of Taiwanese and Cantonese these speakers would use sentences like the following, which has a perfective value:

\[(87) \text{1sg PF write-wrong that-CL character} \quad \text{'I wrote that character wrong} \]

The regular negative counterpart of (87) would be:

\[(88) \text{1sg NEG write-wrong that-CL character} \quad \text{'I didn't write that character wrong} \]

According to Li & Thompson (1981:421) mei negates the completion
of an event. Note that the negative element mei is optionally followed by you. The same phenomenon may be observed in copula constructions which in the affirmative require you, as in:

(89)  mei (you) ren zai waimian
      NEG (COP) person LOC outside
      'There's no one outside'

(90)  wo mei (you) qian
      lsg NEG (COP) money
      'I don't have any money'

This seems to indicate that sentences like (87)-(88) can be analyzed in terms of the underlying structures that were hypothesized for sentences like (89)-(90), as in:

(91)  \( (x_1: \text{wo } (x_1))_{\text{Theme}} (\text{Neg})(\phi)_{\text{Loc}} \{e_1: [\text{xie-cuo}_{\text{y}} (x_1)_{\text{Ag}}
    \quad (x_j: \text{zi } (x_j))_{\text{Go}} \} (e_1) \}\)

A paraphrase for this representation would be: 'there is/isn't my writing that character wrong'.

The question now is how, if this analysis is correct, the completion/non-completion value of the construction should be explained. Recall that in 3.1 the predicate frame used in (91) was said to express the semantic relation reality. The existence of a SoA is at the same time its reality. A tentative explanation for the perfective interpretation of (91) could be that a SoA is conceptualized as 'being in the world' or 'real' once it is completed and 'not being in the world' or 'unreal' if it is not completed.

Statements like these can most easily be made with respect to past events. A further step in the grammaticalization of you/mei (you) therefore could involve its reinterpretation as a past tense marker. In some restricted cases (see Li&Thompson 1981:429) mei(you) has acquired the status of a past tense negative particle, which might be a first step in this direction.
4.3. Non-verbal auxiliary constructions with the copula shi.

A final construction to be dealt with is the so-called (shi) ... de construction. Here are some examples:

(92) ta (shi) zuotian lai de
    3sg (COP) yesterday come de
    'The situation is that she arrived yesterday'

(93) zhei-ben xiaoshuo (shi) wo muqin xie de
    this-CL novel (COP) 1sg mother write de
    'This novel is written by my mother'

These examples manifest some structural similarities with the term-predicates based on an adjective or a possessive predicate (3.1) and the focus construction (3.2): the presence of the particle de, and the optional presence of the copula shi.

Li & Thompson (1981:590) note that constructions like (92)-(93) are appropriate to explain a situation. The sentence given in (92) could be used to give an answer to a question like 'Why couldn't he speak English', whereas its counterpart (94) could be used as an answer to 'Has he arrived yet?':

(94) ta zuotian lai le
    3sg yesterday come PF
    'He came yesterday'

One could say that in (92) the speaker explains a present situation by referring to a past event. The event referred to may also be located in the present or (near) future, as in:

(95) wo (shi) gen ni kaiwanxiao de
    1sg (COP) with 2sg joke de
    'I'm joking with you'

(96) women (shi) bu hui gifu nimen de
    1pl (COP) NEG likely bully 2pl de
    'We aren't going to bully you'
Dik (1985:9) recognizes a category of Phasal Aspect distinctions which '... serve to describe what is the case at some reference point on the temporal axis in relation to the occurrence of some SoA'. Applying this characterization to (92), (93), and (95) yields paraphrases like 'She is someone who arrived yesterday', 'This novel is one that my mother wrote' and 'I am someone who jokes with you'. Representations which reflect this interpretation of are given in (97)-(99):\(^{20}{ }^{21}

\[
\text{(97) Pres } e_j : [ \{(x_i^1 : \Phi_N (x_i^1)) \text{ Past } e_i : \text{Lai}_V (R_i x_i^1) \text{Ag } (e_i) : \\
\text{zuotian } (e_i^1)) (x_j : \text{ta } (x_j)) \phi ] (e_j)
\]

\[
\text{(98) Pres } e_j : [ \{(x_i^1 : \Phi_N (x_i^1)) \text{ Past } e_i : xiaoV (x_j : \text{muqin } (x_j) \text{Ag } (R_i x_i^1) \text{Go } (e_i))) (dx_k : \text{xiaoshu } (x_k) \phi ) \} (e_j)
\]

\[
\text{(99) Pres } e_j : [ \{(x_i^1 : \Phi_N (x_i^1)) \text{ Pres } e_1 : \text{kaiwanxiao}V (R_i x_i^1) \\
(dx_j : \text{ni } (x_j)) \text{Com } (e_i)) (x_k : \text{wo } (x_k) \phi ) \} (e_j)
\]

A literal paraphrase for (97) would be: 'she is someone who is characterized by her arriving yesterday'. The presence of the anaphoric nominal predicate accounts for the occurrence of de, while the term-predicate analysis accounts for the optional appearance of shi.

An problem often mentioned with respect to the analysis of the (shi) ... de construction is illustrated in (100), taken from Hashimoto (1969:100):

\[
\text{(100) ta } (\text{shi}) \text{ zuotian mai de shu } \\
3sg (\text{COP}) \text{ yesterday buy de book}
\]

'He (is someone who) bought books yesterday'

The problem here is the position of de, which would normally mark the end of the headless relative. Hashimoto (1969) approaches this problem from the point of view of the object: how can the inverted position of the object be explained? I would like to look at the problem from the opposite direction: how can the in-
verted position of de be explained?

Looking at the problem from this angle, the most important feature of (100) is that de has ended up in a position next to the predicate, the preferred position for predicate operators. This might point in the direction of a certain grammaticalization of the (shi) . . . de construction. The direction of this grammaticalization can be derived from one of the restrictions on the appearance of de following the predicate. There are several restrictions with regard to constructions like (100), one of which is that the SoA designated by the headless relative must be situated in the past. This might indicate that out of the different phasal aspect distinctions which may be expressed by the regular (shi) . . . de construction, the resultative variant is selected for a treatment which might lead to an incorporation of de in the group of regular aspect markers in Mandarin.

5. Explanations for the use of shi and you

A final question to be answered is why Mandarin should use copulas at all. Except for the obligatory uses of shi, where its occurrence may be said to be motivated by the fact that polarity operators have to be expressed on a bare predicate (Adjective or Verb), there does not seem to be an obvious answer to this question. In this section I have one more look at you and shi and try to give some explanations for the existence of copula support in Mandarin.

5.1. You

Although many languages show a restricted use of a copula, it is hard to find languages which do not use a copula (or some other verb) in the existential construction. The reason for this becomes apparent if one considers the underlying structure for an existential construction:

(101) \(((\forall)_{\text{Loc}}) (x_1: \text{boy } (x_1))\)
Given the fact that the locative predicate is empty, the resulting expression, if no copula were inserted, would be:

(102) A boy

The use of a single term as a full predication, as in (102), although perhaps possible in exclamatives, would cause a lot of ambiguity, as a result of the fact that it makes no sense to refer without at the same predicking something of the entity referred to. This leads to an explanation of the obligatory appearance of you in non-negative existential constructions: its occurrence 'reveals' the presence of the underlying empty predicate. As such you functions as a sign of (existential) predication.

In negative contexts you is optional. If one accepts that the use of mei as a non-completion marker can be analyzed in terms of an underlying existential construction (see 4.2), mei can only be used in existential constructions. Given that mei gives expression to a predicate operator, it can by itself fulfill the same function as you.

The same explanation can be applied to you constructions with a sentence-initial locative or possessive phrase under the Theme, Predication analysis (2.1, 2.2). Under this analysis, the conditions within the predication are the same as those in (101), as in:

(103) \((x_i)\text{(Loc/Poss)Theme}, \{(\phi)\text{Loc}\} (x_j)\phi\)

The explanation used here is not valid for those constructions in which the zai phrase should be analyzed as a predicate. A distinction has to be made here between the locative predicate following you and the sentence-initial zai phrase, which, as I suggested in 2.1, might be ambiguous between a theme and a predicate reading.

With respect to the locative predicate following you, it should
be noted that zai originally was a verb, meaning something like 'to live' or 'to stay'. In the context of an existential predication, it may have been used to give a further qualification of the entity the existence of which was predicated. The development of the zai phrase into a locative predicate would then run parallel to the development of zai from a main verb to a preposition through its use in serial verb constructions.

Under the Predicate analysis of the sentence-initial locative phrase (see 2.1) the Theme, Predication construction given in (108) could have been the source for the locative predicate construction. The examples of the equivalent construction in Classical Chinese given by Graham (1967:6) seem to point in this direction. Consider:

(104) Sung yu fu jen
     Sung COP rich man
     'There was a rich man in Sung'

This example, like the others given in Graham (1967), shows a sentence-initial constituent specifying the location, which has no locative case marking. Within the analysis given in 2.1 this would qualify the sentence-initial constituent unambiguously qualify for Theme status.

I suggest that the occurrence of you in constructions with a locative predicate can be explained as a result of the development of you from a primarily existential copula to a copula of wider application through reinterpretation of the serial verb construction on the one hand, and the Theme, Predication construction on the other.

5.2. Shi

That shi is not entirely optional can be derived from some of the conditions under which its presence is preferred. Consider the following examples, taken from Hashimoto (1969):
The examples given here are ambiguous between a term and a predication interpretation. To render the second reading unambiguously, either shi or a pause should be inserted in between the two constituents. Insertion of a pause results in a Theme, Predication construction, where the pause signals the beginning of a predication. Insertion of a copula marks a predicative relation within the predication. In both cases the predication interpretation is imposed upon the construction.

A second condition under which shi is strongly preferred is illustrated by (106), taken from Li & Thompson (1977:422):

(106) chi pingguo de nei-ge ren shi wo xihuan de peng-you
      eat apple de DEM-CL person COP lsg like de friend
      'The person who is eating an apple is the friend I like'

If the subject term in classifying constructions is long and complex, as in (106), the insertion of a copula is preferred. Junger (1981:127), discussing a similar construction in Hebrew, notes that the function of the copula in sentences like these is to separate the Subject term from the predicate so as to ease the processing of the sentence.

These uses can most easily be understood in the light of the history of shi. Li & Thompson (1977) note that shi began its career as a copula as a demonstrative pronoun. In Archaic Chinese it came to be used as a pronoun resuming the Theme in a Theme, Predication construction, as in:

(107) ji yu qi sheng you yu qi si, shi huo ye
      already wish him live also wish him die,DEM indecision FP
      'Wishing him to live while wishing him to die, that is indecision'
The pronoun shi here resumes the complex Theme. According to Li & Thompson (1977:424) the Theme, Predication (Topic, Comment in Li & Thompson's terminology) construction gradually developed into 'a subject-predicate construction with the anaphoric demonstrative pronoun shi being reanalyzed as a copula'. Junger (1981) observes a similar phenomenon in Hebrew and explains this development in terms of markedness shift (see Dik 1978:111). Traces of the development of shi under this analysis, which I find quite plausible, can still be found in the present uses of shi: the conditions which motivated its development into a copula are the same as those under which it is strongly preferred.

Note that the shi constructions present a mirror image of the you constructions (with a sentence-initial locative phrase): whereas the non-existential copula uses of the latter were hypothesized to be the result of reinterpretation of the Theme, Predication construction as a Predicate Subject relation, the former are hypothesized to be the result of reinterpretation of the Theme, Predication construction as a Subject Predicate relation.

6. Copula support rules in Mandarin

By way of conclusion, I will now try to capture the different conditions for the insertion of a copula in a number of support rules. Separate rules are given here for the optional and obligatory uses of shi and you.

Starting with you, the rules may be formulated as in (108)-(109):

(108) OBLIGATORY YOU SUPPORT

| input:    | π predicate_β (αα₁) ≠ |
| conditions: | π ≠ Neg |
|           | β = {α₁}_yf |
|           | α = 1 |
| output:   | π youᵥ predicate_β (αα₁) |
Optional You Support

(109) \text{OPTIONAL YOU SUPPORT}

\begin{align*}
\text{input:} & \quad \pi \text{ predicate}_\beta (\alpha_1) \\
\text{conditions:} & \quad \pi = \text{Neg} \\
& \quad \beta = \{ (\alpha_1) \text{sf} \} \\
& \quad \alpha = 1 \\
\text{output:} & \quad \pi \ you_v \ \text{predicate}_\beta (\alpha_1) \\
\end{align*}

These rules account for the appearance of you in constructions based on adpositional predicates, in which the \#-argument is indefinite: existential and locative constructions (2.1), possessive constructions (2.2), and the perfective auxiliary construction (4.2). You support is obligatory except if the predicate operator Neg is present, in which case mei, the expression of Neg in an existential context, is optionally followed by you.

Turning to shi, the rules given in (103)-(104) may be formulated:

Obligatory Shi Support

(110) \text{OBLIGATORY SHI SUPPORT}

\begin{align*}
\text{input:} & \quad \pi \text{ predicate}_\beta (\alpha_1) \\
\text{conditions:} & \quad \pi = \text{Pos, Neg} \\
& \quad \beta = \{ (\alpha_1) \} \\
\text{output:} & \quad \pi \ shi_v \ \text{predicate}_\beta (\alpha_1) \\
\end{align*}

Optional Shi Support

(111) \text{OPTIONAL SHI SUPPORT}

\begin{align*}
\text{input:} & \quad \pi \text{ predicate}_\beta (\alpha_1) \\
\text{conditions:} & \quad \pi \neq \text{Pos, Neg} \\
& \quad \beta = \{ (\alpha_1) \} \\
\text{output:} & \quad \pi \ shi_v \ \text{predicate}_\beta (\alpha_1) \\
\end{align*}

These rules account for the appearance of shi in constructions which are based on a term/predication-predicate, including the derived adjectival and possessive construction (3.1), the cleft and pseudo-cleft construction (3.2), the veridical construction (3.3), and the (shi) \ldots de construction (4.3). Shi support is
optional except if the predicate operator Neg or Pos is present, and therefore presents the mirror image of You support. Note that the Pos operator is restricted to those affirmative sentences in which positive polarity is made explicit, i.e. overtly expressed or stressed, as in the veridical construction.

In addition to these support rules the use of shì as a focus marker was accounted for by rule (70) given in 3.2, which is repeated here for the sake of convenience:

(112) \[(x_n)^{Pos} \rightarrow shì (x_n)\]
Notes

1. Thanks are due to Simon Dik, Shen Jia Xuan, and the editors of WPFG for valuable comments on an earlier version of this paper.

Abbreviations used in this paper: CSH = Copula Support Hypothesis, FG = Functional Grammar, SoA = State of Affairs; Glosses: ASP = Aspect, CL = Classifier, CONN = Connective, COP = Copula, DEM = Demonstrative, DIR = Directional, DUR = Durative aspect, EMPH = Emphatic, FP = Final particle, LOC = locative case marker, NEG = Negative, NOM = Nominalizer, PERF = Perfect, PF = Perfective, POS = Positive, sg = singular, pl = plural; Representations: Semantic functions: Ag = Agent, Go = Goal, Rec = Recipient, φ = Zero, Loc = Location, Poss = Possessor, Com = Comitative, sf = any semantic function; Syntactic functions: Subj = Subject; Pragmatic functions: Foc = Focus; Predicate operators: Asp = Aspect, Pf = Perfective, Pres = Present, Neg = Negative, Pos = Positive; Term operators: d = definite, i = indefinite, l = singular, m = plural, A = anaphoric operator, R = relative operator; Word classes: A = Adjective, N = Noun, V = Verb.

3. Note that saying that a copula is optional is tantamount to saying that the exact conditions under which it is obligatory have not yet been determined, or are hard to formalize. The main function of shi is to ease the processing of long and complex terms, inserted in the φ-argument position, but it is hard to specify how long and complex a term should be to make the predication quality for shi-support.

4. Within the CSH-approach it is not necessary to classify the adjectives involved as a special subclass of stative verbs.

5. See also Hannay (1985).

6. Since locative postfixes in Mandarin Chinese have a number of nominal characteristics, I analyze them as part of the predicate rather than as the expression of locative semantic functions.

7. See Li & Thompson (1981:15) on the 'Topic Prominence' of Mandarin. Their definition of Topic coincides with that of Theme in FG. See Shen (1987b) for a FG analysis of Themes in Mandarin.

8. See Dik (1978:ch.6) for some Russian examples of the same phenomenon.

10. See also Clark (1978) who, following Lyons (1967, 1968), groups together possessive, locative and existential constructions in one class of 'locationals'.
11. I leave out of consideration here the question of how abstract concepts such as 'love' and 'hate' should be classified. This question does not affect the present discussion.

13. The group of adjectives which can be applied to third order entities is very limited. Examples are true, convincing, and undeniable. I restrict myself to first and second order entities here.

14. The underlying structure given in (52) is intended to capture both the cleft and the pseudo-cleft construction. The differences in the expression of the two constructions can be captured by placement rules. See Dik (1980:ch.10) for an elaboration of this point.

15. It could be that in some contexts 'illogical' copula sentences should be analyzed as veridical constructions, which in some respects are structurally similar to focus constructions (see 3.3).

16. See Mackenzie (1986) and Shen (1987b) on the application of predication predicates in other contexts.

18. See also Moutouakil (1986).

19. For instance, the assertive particle -dir in Turkish developed out of a copula. In the latter function it is only sporadically found in contemporary Turkish.

20. See Vet (1986) for the representation of tense and time adverbials used here.

21. There are no grammatical Tense distinctions in Mandarin. The Tense operators used in these representations are simply meant to represent the understood temporal reference points. I do not mean to imply that Tense operators are a necessary element of a FG of Mandarin.

22. Another restriction is that the resulting construction should not cause ambiguity. Ambiguity arises easily with human objects where the subject of the main clause is human too, as in (i) (see Hashimoto 1969:100):

   (i) ta (shi) gunian sheng de xiaohair
       3sg (COP) last.year born de child
       'She is a child who was born last year/She gave birth to a child last year'

In the case of sentences like (100) an interpretation like 'He is a book that was bought yesterday' would not be a likely one.

(a) Transfer the required amount of money to postal account (giro) no. 5923629, in the name of C.H.M. Kroon - inz. WPFG-, Amsterdam;
(b) Send a (Euro)-cheque or, from abroad, an international money order written out in Dutch guilder to the editorial address.

Please specify the required items.
For standing orders contact the above address.

The following papers are now available:

10. A. Moulaouakil - Towards an adequate representation of illocutionary force in FG. Hfl 5.00.
13. Albert Rijksbaron - The pragmatics and semantics of conditional and temporal clauses; some evidence from Dutch and Classical Greek. Hfl 6.00
17. Lourens de Vries - The Wambon relator system. Hfl 6.00
18. Simon Dik - Two papers on the computational application of FG. Hfl 6.00.
24. Hetty Voogt - Constructing an FG lexicon on the basis of LDOCE. Hfl 5.00.
30. Peter Harder - The instructional semantics of conditionals. Hfl. 5.00.

Also available are Simon Dik's 1978 monograph Stepwise lexical decomposition (Hfl 5.00) and a complete bibliography of FG books, articles and papers (Hfl 2.50). These items can be ordered in the same way as a Working Paper.
